Tesamorelin

What is Tesamorelin?

Tesamorelin is a synthetic peptide that stimulates the pituitary gland to release the body's own growth hormone. It is classified as a Growth Hormone–Releasing Hormone (GHRH) analog and works by enhancing natural GH signaling rather than supplying external hormone. Tesamorelin is best known for its ability to target and reduce visceral fat, the deep abdominal fat linked to metabolic and cardiovascular risk. It also supports improved body composition, healthier metabolic markers, and overall hormonal balance. Some patients notice gradual changes in waist circumference and fat distribution over 8–12 weeks, with continued improvements over several months of consistent use.

What Forms of Tesamorelin Are Available?

Tesamorelin is available as a small subcutaneous injection, typically once daily.

How Does Tesamorelin Work?

- Stimulates the pituitary gland to increase natural growth hormone release
- Increases IGF-1 levels, supporting fat metabolism and tissue regulation
- Specifically targets visceral abdominal fat stores
- Improves lipid metabolism and insulin sensitivity
- Supports healthier energy utilization and metabolic balance
- Encourages favorable changes in body composition over time
- Supports sleep quality by enhancing natural hormone rhythms
- Works synergistically with diet and exercise for sustained results
